Final Validation

Enrique Calderon

LIDSoL

Semester 2026-2

Final Validation Overview

Goal

Everyone verifies that the app is reachable from another host over HTTPS and resolves common deployment issues.

Duration

30 minutes

Final Practical Check

By the end of the workshop, each attendee (or pair) demonstrates their deployed endpoint from an external machine:

- App responds on the expected route (HTTPS).
- Using environment variables correctly (Output varies based on `.env`).
- Firewall correctly blocking non-permitted traffic (e.g. Can't hit port 5000 directly).
- Service starts automatically on reboot (Systemd).

Let's verify HTTPS Reachability

From a classmate's machine, or another terminal:

```
curl -v https://your.public.domain -X POST \
  -H "Content-Type: application/json" \
  -d '{"secret_key": "supersecretkey"}'
```

- Are you getting `HTTP/2 200`?
- Check your Nginx proxy logs if not:

  ```
  sudo tail -f /var/log/nginx/access.log
  ```

- Check your Flask app logs if the request is reaching it:

  ```
  journalctl --user -u my-flask-app -f
  ```

Service Automation Validation

Restart your VM/VPS, and see if it automatically recovers:

```
sudo reboot
ssh user@your-vps-ip

sudo systemctl status nginx
systemctl --user status my-flask-app
```

Conclusion & Next Steps

- Congratulations on deploying your first FOSS service with secure HTTPS access!
- Next steps:
  - Explore more complex apps, maybe with databases or multiple services.
  - Learn about monitoring and logging for production services.
  - Consider deploying on a cloud provider or using orchestration tools like Kubernetes for larger projects.

Thank you for participating, and happy coding!
